APPENDIX

Geographic Region Maps – Red knot critical habitat (migratory stopover and wintering/nonbreeding areas)

These important habitats are classified as “Critical” or “Suitable” according to the following criteria:

“Critical” habitats (red) are:
1) sites of known importance for red knots and are documented by survey
2) sites of known importance by expert opinion, and may or may not have survey data available
3) sites of known importance that are occupied intermittently (because of naturally fluctuating food resources, human disturbance, beach replenishment, etc.), and may or may not have survey data.

“Suitable” habitats (green) are:
1) sites of known importance that are occupied intermittently, may or may not have survey data, and are deemed by expert opinion as secondary sites not critical to the persistence of the red knot population at its current population level -- these sites may become critical if the red knot population increases
2) sites that were historically used by red knot but are now unused although the habitat has not been altered -- these sites may become critical if the red knot population increases.
