## ACKNOWLEDGEMENTS

This report would not have been possible without the significant contributions from environmental scientists at the New Jersey Department of Environmental Protection and the United States Environmental Protection Agency. Leslie McGeorge, Alena Baldwin-Brown, Alfred Korndoerfer, Victor Poretti, and Dean Bryson of NJDEP Water Monitoring and Standards provided useful editorial comments and interpretation of results. Jim Kurtenbach at U.S. EPA Region 2 provided guidance on the Network's design and implementation.

### Round 4 Benthic Macroinvertebrate Data

#### Volume 1 of 2

#### EXECUTIVE SUMMARY

Biological monitoring of freshwater systems in New Jersey provides an effective means of gauging long-term trends in surface water quality throughout the State. The Ambient Biomonitoring Network (AMNET) is one of the major ongoing monitoring programs. This statewide network of over 760 non-tidal AMNET stations employs sampling and taxonomic analysis of in-stream macroinvertebrate communities to assess the ecological condition at each station. An integrated index of "biometrics", based on community composition and pollution tolerance levels of individual taxa, is used to assign assessment ratings.

Between the start of the AMNET program (1992) up until 2004, a single statewide index, the New Jersey Impairment Score (NJIS), was used in assigning one of three assessment ratings, non-impaired, moderately impaired, and severely impaired. The NJIS was limited in that it used family level taxonomic identification for calculating scores and did not account for geographical differences in macroinvertebrate community structures. To resolve these limitations, starting with the mid 2004 data (Atlantic Region report), three indices are used for assessments; High Gradient Macroinvertebrate Index (HGMI), Coastal Plain Macroinvertebrate Index (CPMI), and Pinelands Macroinvertebrate Index (PMI). These indices account for the State's geophysically different ecoregions and use genus level taxonomic identification for calculating scores. The higher level of identification allows for more resolute and accurate results at four assessment rating levels (rather than the three previously used); "excellent", "good", "fair", and "poor". The results are considered reflective of the water and/or habitat quality at each site. This information is used by the Department, primarily in assessing progress toward the goals of the Clean Water Act via the Integrated Water Quality Monitoring and Assessment Report. AMNET data are also integral for designation of Category 1 waters, based on exceptional ecological significance.

Figure 1

Results are reported separately for each of New Jersey's five major drainage basins or "Water Regions" (Lower Delaware, Upper Delaware/Northwest, Northeast, Raritan, and Atlantic), each encompassing several sub-basins ("Watershed Management Areas"). The Water Regions, with an average of 153 non-tidal AMNET sites each, are sampled in consecutive years on a five-year rotational basis. The most recent results (posted by the end of the calendar year sampling is completed for a region), and Round by Round comparisons along with raw data, can be found at:

<http://www.state.nj.us/dep/wms/bfbm/amnetRnd4.html>

The present study area comprises the Upper Delaware/Northwest Water Region, and includes those sub-basins that drain to the Upper Delaware River, namely: WMA #'s 1 (Upper Delaware River tributaries), 2 (Upper Wallkill River system), and 11 (Central Delaware River tributaries). This report presents the results for the biological monitoring conducted from July 2007 - June 2008 (see Map 1, page 4). The sampling of the Upper Delaware/Northwest Water Region marks the fourth round of data collection for this basin. The results obtained in the fourth round are similar to those of the previous (third round) of sampling. Currently, of the 138 AMNET sites sampled in the Upper Delaware/Northwest Water Region, 41 (29.7%) were found to exhibit "excellent" benthic macroinvertebrate communities, with 49 (35.5%) exhibiting "good", 39 (28.3%) "fair", and 9 (6.5%) exhibiting "poor" benthic communities ( See Figure 1).

In order to generate trend information, results from the current (Round 4) sampling were compared to those from the same sites sampled in the earlier round (Round 3). For the purposes of comparing the two rounds, Round 3 results were re-assessed using the new indices. Of the 138 AMNET sites sampled in the Upper Delaware/Northwest Water Region, the Round 4 samplings yielded sites with more "excellent" (29.7%) and "good" (35.5%) ratings than did the third round sampling (23.2% and 34.1% respectively). Conversely, the number of "fair" (28.3%) and "poor" rated sites (6.5%) observed in the Round 4 sampling has declined since the Round 3 sampling (30.4% and 12.3% respectively). Figure 2 displays the percentage of change in rating among the same 138 AMNET sites in the Upper Delaware/Northwest Water Region that were sampled during the third round study period, and again during the current (Round 4) study period. The green indicates sites that have undergone a positive change, yellow indicates no change, and red indicates a negative change. Positive change is defined as an improved rating from the previous Round's rating, while a negative change is defined as a downgraded rating from the previous Round. Individual results and changes in each site can be found in Table 4, Volume 2.

Figure 2

Figure 3 compares the results of each round of sampling in the Delaware/ Northwest Region. The percentage of excellent, good, and severe results remained relatively stable from round 1 to round 4. Earlier rounds of data were recalculated using the new indices. Some sites sampled in Round 1 were collected outside of the April – November sampling period criteria specified for the newly implemented indices. Results from these samples may not have the same degree of accuracy as those collected within the sample period criteria. More robust statistical analysis will be used in the future, if necessary, to compare significant differences between Rounds.

Figure 3

Assessment Rating	Round 1	Round 2	Round 3	Round 4
Excellent	22.0%	32.8%	23.4%	29.7%
Good	34.5%	31.4%	34.0%	35.5%
Fair	27.1%	29.2%	30.5%	28.3%
Poor	16.4%	6.6%	12.1%	6.5%

As reflected in the present study results, human land uses and practices, superimposed on the undisturbed physical terrain, play a major role in controlling the degree of pollution or degradation in a stream system.

The relationship between benthic macroinvertebrate community impairment has been statistically related to different physiographic land types, land uses and other anthropogenic factors, on a statewide basis\*.

These findings concludes the following:

- 1) Invertebrate communities are commonly impaired in urban streams;
- 2) Invertebrate community impairment was related to total urban land and total wastewater flow upstream of a site;
- 3) Changes in aquatic community structure were statistically related to environmental variables along the urban gradient – that is to say that such things as impervious surfaces were related to a negative response in the aquatic invertebrate community.

To determine what factors are contributing to impairments, or changes in impairment ratings, the Department has established a Stressor Identification (SI) process. The purpose of the Stressor Identification (SI) process, as developed by USEPA, is to identify the principle stressor(s), including but not limited to specific pollutants, responsible for the degraded biological condition. Determining the probable cause or causes of this biological impairment, whether it be a chemical pollutant or a non-chemical stressor such as flow alteration or siltation, is the first step towards deciding whether a TMDL or other appropriate management measures will be taken to remediate the impairment. Currently, there are no SI studies in this Water Region.

### **Additional Information**

Additional Information on the AMNET program can be obtained from the WM&S' Bureau of Freshwater & Biological Monitoring by calling 609-292-0427 or visiting its website at: <http://www.state.nj.us/dep/wms/bfbm>

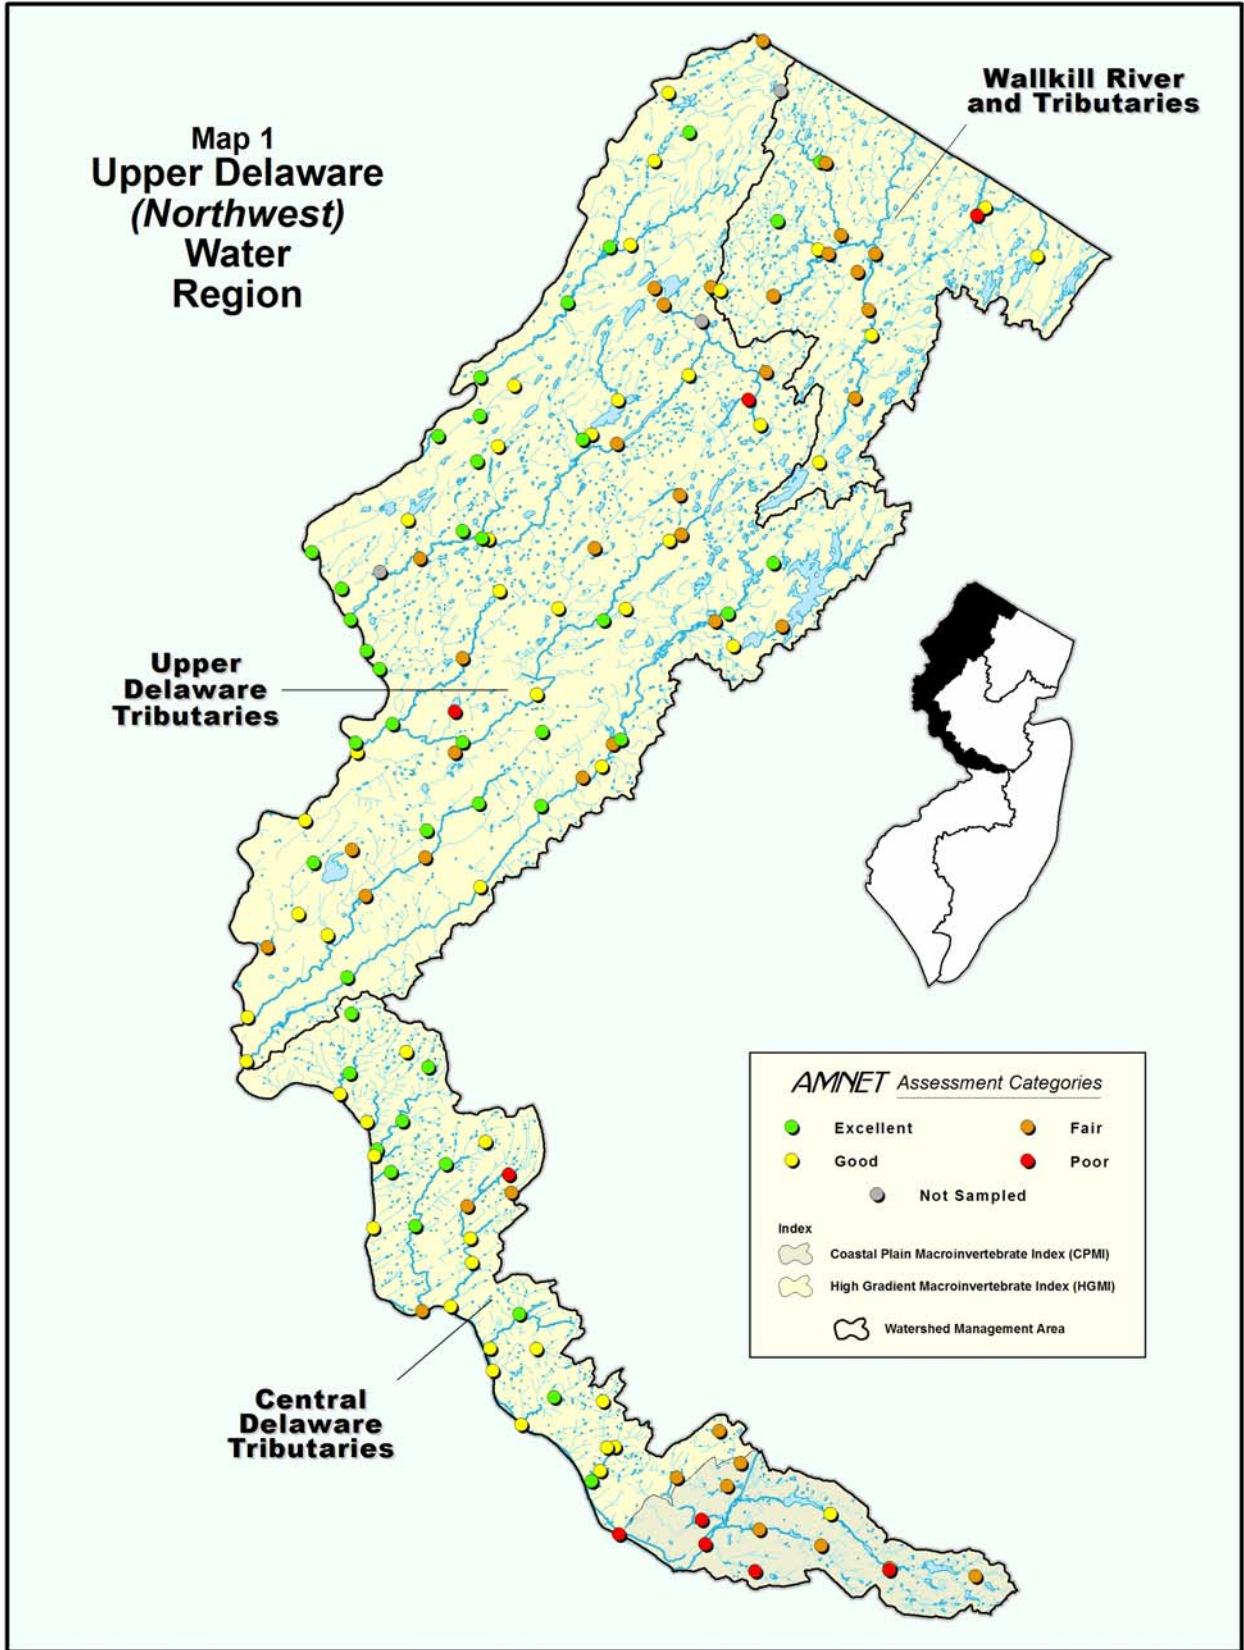

Raw data is posted on this website by the end of the calendar year that the data is received and validated. GIS shapefiles will also be available on the NJDEP web site once all data is reviewed and finalized.

Additionally, raw data is submitted to WQX as soon as the data is received and validated. WQX is USEPA's repository and framework for water quality, biological, and physical data. It is used by state environmental agencies, EPA and other federal agencies, universities, private citizens, and many others to store data. The retrieval of the data is handled through the STORET interface and can be accessed at: <http://www.epa.gov/storet>

Comments are welcome and may be emailed to: [bfbm@dep.state.nj.us](mailto:bfbm@dep.state.nj.us).

## INTRODUCTION

### **Rationale for Biological Monitoring**

Biological monitoring of freshwater systems in New Jersey provides an effective means of gauging long-term trends in surface water quality throughout the State. The Ambient Biomonitoring Network (AMNET) is one of the major ongoing monitoring programs. This statewide network of over 760 AMNET stations employs sampling and taxonomic analysis of in-stream macroinvertebrate communities to assess the ecological condition at each station. An integrated index of "biometrics", based on community composition and pollution tolerance levels of individual taxa, is used to assign assessment ratings; specifically the High Gradient Macroinvertebrate Index (HGMI). Biological monitoring, as referenced in this report, pertains to the collection and analysis of stream macroinvertebrate communities as indicators of water or habitat quality. Macroinvertebrates are larger-than-microscopic, primarily benthic (bottom-dwelling) fauna, which are generally ubiquitous in freshwater and estuarine environments, and play an integral role in the aquatic food web. Insects (largely immature forms) are especially characteristic of freshwaters; other major groups include worms, mollusks (snails, clams) and crustaceans (scuds, shrimp, crayfish, etc.). They are more readily collected and quantified than either fish or periphyton communities. Species comprising the in-stream community occupy various niches, based on functional adaptation or feeding mode (e.g. predators, filter or detritus feeders, scavengers); their presence and relative abundance is governed by environmental conditions (which may determine available food supply), and by pollution tolerance levels of the respective taxa. The overall community thus is holistically reflective of conditions in its environment. Assessments of ambient water / habitat quality can then be made based upon standardized procedures, which can show perturbations measured as changes or differences in community structure [1]. While development of a "multitrophic" approach, to include finfish and periphyton communities with invertebrates is being investigated, the primary means of assessment to date has been through macroinvertebrate community analysis.

#### ***Advantages of Using Benthic Macroinvertebrates:***

1. They are good indicators of localized conditions of water quality due to their limited mobility. As such, they are well suited for the assessment of site-specific pollution impacts.
2. They are sensitive to environmental impacts from both point and non-point sources of pollution.
3. They integrate the effects of short-term environmental variations, such as oil spills and intermittent discharges.
4. Sampling is relatively easy and inexpensive.
5. They are holistic indicators of overall water quality, even for substances that may be present but at lower than detectable levels.
6. They are normally abundant in New Jersey waters as well as aquatic environments in general.
7. They serve as the primary food source for many species of commercially and recreationally important fishes.
8. Unlike chemical monitoring, where impacts to the environment tend to be by inference, not direct determination, they provide a direct measure of water quality in a manner consistent with the goals of the Clean Water Act.
9. They can be used to assess nonchemical impacts to the aquatic habitat, such as by thermal pollution, excessive sediment loading (siltation), or eutrophication.
10. To the general public, impacts to resident benthic macroinvertebrate communities are more tangible measurements of water quality than more esoteric listings of chemical test results.
11. When monitored together with relevant chemical/physical parameters, benthic macroinvertebrate communities can be used to identify sources of impairment.

#### ***Limitations of Biological Monitoring:***

Biological monitoring cannot replace chemical monitoring, toxicity testing, and other standard environmental measurements. Each of these tools provides the analyst with specific information available only through its respective methodology.

The following illustrations provide an overview of the major macroinvertebrate indicator groups employed in making biological water quality assessments.

***Benthic Macroinvertebrates Usually Indicative of Good Water Quality***

Mayfly nymphs are often abundant wherever the water is clean. They are sensitive to various types of water pollution, including low dissolved oxygen, ammonia, biocides, and metals.

Stonefly nymphs are usually found only in cool, well-oxygenated waters free of pollution. Though not usually found in the numbers characteristic of mayflies, the presence of even a few stoneflies is indicative of good water quality.

Most caddisfly larvae, many of which build portable cases of stones, sticks, sand, and other detritus, are intolerant of water pollution.

Aquatic beetles are common in well-oxygenated, swiftly running waters; many species are referred to as “riffle beetles.” They are usually indicative of clean water since they are sensitive to wetting agents (soaps and detergents) and other pollutants.

All photographs taken by D.Bryson, NJDEP

***Benthic Macroinvertebrates Usually Indicative of Poor Water Quality***

Midges (chironomids) are among the most common of aquatic invertebrates. They occupy a variety of aquatic habitats, including lakes, ponds, bogs, rivers, creeks, and marshes. They even exploit manmade habitats such as sewage treatment plants, water treatment plants, fish pools, irrigation ditches, and birdbaths. Many species are very tolerant of pollution.

Aquatic sowbugs, or freshwater isopods, are abundant in waters enriched with organic nutrients and low in dissolved oxygen. They are commonly observed in the recovery areas below sewage treatment plants.

Leeches and other segmented worms are very common in our lakes and streams, though not often noticed. They are tolerant of poor water quality and severe pollution.

Black fly larvae are filter feeders, capturing and ingesting plankton and bacteria from the surrounding water with specialized antennae. Some species are very tolerant of poor water quality and thus can be used as indicators of pollution.

## STUDY DESIGN

### Data Quality Objectives

The major goal of AMNET is to provide a long-term, cost-efficient means of gauging the quality of surface waters and watershed areas throughout the State. This is accomplished through biological sampling and analysis from a network of stream sites that adequately represents New Jersey's five major drainage basins and NJDEP's Watershed Management Areas (WMA). Administratively, a total of 21 WMA's have been delineated within New Jersey's five basins. Each major basin constitutes a "Water Region"; a major sub-basin forms each WMA. Within each WMA are several smaller sub-basins, delineated by the United States Geological Survey (USGS) as "hydrologic units," scale 11 (HUC11). The present study area comprises the Upper Delaware/Northwest Water Region, and primarily includes all New Jersey sub-basins draining to the non-tidal Delaware River, extending northward from Trenton Falls; it also includes the Wallkill River sub-basin. The region falls primarily within the Kittatinny Ridge and Valley, Reading Prong and Piedmont ecoregions, encompassing largely upland forest with high-gradient terrain. The study area of the present report includes WMA #'s 1 (Upper Delaware River tributaries), 2 (Upper Wallkill River system), and 11 (Central Delaware River tributaries) (see Maps 1 – 8, Volume 2). The standard sampling interval of five years, reflects a realistic temporal lag between cessation of an environmental perturbation and recovery of the impacted biological community. The Integrated Water Quality Monitoring and Assessment Report [2], which re-examines changes in New Jersey's stream systems on a two-year cycle, has indicated that five years is an optimum period for long-term biomonitoring. An ample network of stations is required for the creation of a long-term database, which in turn, is necessary for trend analysis and operation of water quality predictive models.

The AMNET program is designed to monitor a Water Region's complement of stations within a 12 to 15 month time period (depending on the size of the Water Region) giving DEP's modelers and planners a snapshot of ambient biological impacts during that continuous time interval. Sampling occurs during the months of April - November, until all of the sites of the respective Water Region are visited. Sampling is curtailed through the coldest months (December to March), because of difficulties encountered in obtaining representative samples during this period.

### SITE SELECTION

Sites were selected essentially to provide representative coverage of each Water Region, as well as the entire State. To ensure enough flow for sampling, sites on "first-order" streams are situated at least three miles downstream of headwaters (first order streams are those with no tributaries). Since most streams at this level have very little (or only intermittent) flow, most of the AMNET sites are situated on second-order streams (with only first-order streams as tributaries) and higher (with a greater hierarchy of tributaries). All sites are located in reasonably accessible and primarily wadeable segments, proceeding downstream to the head-of-tide. Sites are numbered in approximate upstream to downstream order, from the mainstem of each major sub-basin to each adjacent tributary, and then to the next adjacent sub-basin. This is in an approximate north to south order within the Upper Delaware/Northwest Water Region.

To maximize data correlation, AMNET, wherever possible, incorporates existing stations of the Ambient Surface Water Chemical Monitoring Network, which is administered jointly by NJDEP and the USGS [3]. Furthermore, so as to gauge the effects of major tributaries and larger lakes, many AMNET sites are located near their confluence or outlet. An attempt is made when selecting sites to obtain a sample representative of the stream's total water quality. Sites are located in areas that best represent the stream, Watershed Management Area (WMA) or Hydrologic Unit.

Exact AMNET site locations were determined via the Global Positioning System (GPS) using Trimble

Pathfinder units and the appropriate correction sources utilized by NJDEP. All positions were logged into the NJDEP's Geographical Information System (GIS) (see Maps 1 – 8, Appendix A, Volume 2).

A total of 142 stations had been established in the Upper Delaware/Northwest Region in the previous round (Round 3) [4]. Since then, one site (AN0118) was determined to be tidal and was dropped from the network. This left a total of 141 active sites the Upper Delaware/Northwest Water Region. This area (shown in Figure 4) primarily includes all New Jersey sub-basins draining to the Upper Delaware River system (WMA's #1 and 11) plus the upper Wallkill River sub-basin (WMA #2). The present Upper Delaware/Northwest study area (Figure 4) includes a total of 141 sampling sites, AN0001 – 117 and AN0294 – 309A (see Table 2, Volume 2). Three active sites were not sampled; AN0001 due to lack of flow, AN0020 due to a collection error, and AN0031 was inaccessible because of bridge construction.. This resulted in 138 sites sampled and assessed for Round 4.

**Figure 4**

Map of Round 4 study area

## FIELD & LABORATORY METHODS

Benthic macroinvertebrate sampling and analysis is performed in accordance with the NJDEP Field Procedures Manual [5], Rapid Bioassessment Protocol (RBP) guidelines of the USEPA [6] and Standard Operating Procedures (SOP) (see [http://www.state.nj.us/dep/wms/bfbm/download/AMNET\\_SOP.pdf](http://www.state.nj.us/dep/wms/bfbm/download/AMNET_SOP.pdf)) of the NJDEP Aquatic Biomonitoring Laboratory [7]. As detailed in the SOP and in the quality assurance work plan [8], a thorough quality control program, with emphasis on macroinvertebrate taxonomy, is practiced.

### Sample Collection

In general, a "multi-habitat" approach is used, focusing on the more productive habitat types [6]. The usual sampling device is a D-frame kick net of 800 x 900 um mesh size and one foot width (a Ponar dredge may be employed when conditions require). In high-gradient streams, where the predominant substrate is cobble, the riffle/run area is the preferred sampling habitat; other likely habitat types are sampled when present. The kick net is held firmly against the hard bottom, and an area approximately one foot upstream of the net is disturbed using feet and/or hands. This procedure is repeated, sampling all velocity/depth regimes at the site, including at least one riffle-run-riffle sequence (if present). In the low-gradient Coastal Plain streams, bottoms generally consist of sand or mud without dominant cobble/riffle areas; therefore, a variety of stable substrates including woody debris, submerged macrophytes and portions of banks, are sampled. The "jab and sweep" method [9] is employed; a minimum of 20 jabs/sweeps are taken, proportioned approximately to the numbers of each habitat type present. In all cases, stream distance sampled approaches, but does not exceed, 100 meters. Level of effort is consistent for all sites. Where possible, sampling is done upstream of bridges, sufficiently removed from the influence of any associated channel alterations. The entire sample is sieved using a #30 mesh sieve bucket, put into wide-mouthed (1-L) jars, and preserved with 5 to 10% formalin (to 20% in cases of excessive organic loading). Both the sieve bucket and net are examined for adhering organisms. Any found are removed with forceps and placed into the sample jar. During the field operations, qualitative observations of habitat, surrounding land use, potential pollution sources, and presence of other aquatic biota are recorded (Appendix D, Volume 2); a visual-based qualitative habitat assessment [6] is also performed (see Supplemental Analyses/Evaluation Methods). These observations/evaluations, however do not factor into the final bioassessment rating.

### **Sample Processing and Sorting**

In the laboratory, after rinsing in a #30 mesh sieve to remove the preservative, the composited sample is evenly distributed in a light-colored pan marked with grids of equal size. Using low-power magnification (6.3x), all organisms greater than 2mm in size are then removed from each randomly selected grid until a total of at least 100 organisms is obtained. Colonial groups (e.g. Bryozoa and Porifera), vertebrates, and terrestrial organisms are not included in the subsample. Organisms retained are reasonably intact to allow for accurate identification.

### **Macroinvertebrate Identification and Quality Control**

The individuals from the subsample are identified to the lowest practicable taxonomic level, usually genus or species, using 7 to 30X stereozoom and 40 to 400X compound magnification. Leica Model MZ6 stereomicroscopes and Leica Models DMLS and DME compound microscopes are currently used. A computerized digital camera system projects and records microscope images of selected specimens to aid in their identification. A comprehensive collection of taxonomic keys and other references, including functional (or niche) descriptions and pollution tolerance classifications for most species, is maintained. An indexed list of these is given in the AMNET Program Standard Operating Procedure (SOP) [7]. Pertinent new reference material is added when available. Taxonomists confer with each other regarding species in question. The International Taxonomic Information System (ITIS) ([www.itis.gov](http://www.itis.gov)) is monitored for possible changes in nomenclature or groupings. Consultation with other scientists in the field, particularly from agencies involved in similar programs (e.g. New York Department of Environmental Conservation, USGS, USEPA), provides added assistance and confirmation when needed. For verification, 10% of the samples are sent to a qualified independent consultant for parallel identifications. A macroinvertebrate specimen reference collection is also maintained.

### **Data Analysis**

Biological impairment may be caused by several major factors such as organic enrichment, habitat degradation, or toxicological effects. It may be manifested in several aspects of the benthic macroinvertebrate community; these include absence of pollution-sensitive taxa, especially the EPT group, i.e., Ephemeroptera (mayflies), Plecoptera (stoneflies) and Trichoptera (caddisflies); excessive dominance of pollution-tolerant taxa such as Chironomidae (midges) and Oligochaeta (worms); low overall taxa numbers, or other perceptible differences in community structure relative to a reference condition.

The data analysis is an important part of the RBP protocol. Developed under USEPA auspices as an expedient and cost-effective monitoring tool, it recognizes the use of community metrics and the pollution indicator concept. "Biometrics" measure different components of community structure, including population and functional parameters, each with a different range of sensitivity to pollution stresses [1, 10]. The use of a variety of biometrics assures a more robust or valid assessment; therefore, an anomaly in any one metric is less likely to invalidate the study findings. The results are integrated through common scoring criteria, derived from an established comparable database, to determine a final numerical rating and consequent biological assessment category (see Table 1). This provides the analyst with an easily communicated evaluation of relative impairment, referred to in this report as the "bioassessment rating." For RBP protocols, results are based on 100 organism sub-samples. Scoring criteria for RBP protocols [1] are calibrated for genus level taxonomy, giving four final rating categories ("excellent", "good", "fair", and "poor").

## Multimetric Index Development

Previously, a single statewide index, the New Jersey Impairment Score (NJIS), was used in assigning one of three assessment ratings, non-impaired, moderately impaired, and severely impaired. The NJIS was limited in that it used family level taxonomic identification for calculating scores and did not account for geographical differences in macroinvertebrate community structures. To resolve these limitations, three indices are now used for assessments; High Gradient Macroinvertebrate Index (HGMI), Coastal Plain Macroinvertebrate Index (CPMI), and Pinelands Macroinvertebrate Index (PMI). These indices account for the State's geographically different regions and use genus level taxonomic identification for calculating scores. For the Northwest Water Region assessments, HGMI & CPMI were used. The higher level of identification allows for more resolute and accurate results at four assessment rating levels (rather than the three previously used); "excellent", "good", "fair", and "poor". The results are considered reflective of the water and/or habitat quality at each site. This information is used by the Department, primarily in assessing progress toward the goals of the Clean Water Act via the Integrated Water Quality Monitoring and Assessment Report. AMNET data are also integral for designation of Category 1 waters, based on exceptional ecological significance. New Jersey's benthic macroinvertebrate communities can be statistically grouped into three distinct structures based on geographical regions: high gradient (above the Fall Line), low gradient (Coastal Plain excluding the Pinelands), and Pinelands. To accurately assess biological conditions, a multimetric index was developed using genus-level taxonomic identifications for each distinct region using guidelines outlined in USEPA *Rapid Bioassessment Protocols (RBP) for Use in Wadeable Streams and Rivers* (see <http://www.epa.gov/bioindicators/html/rbps.html>) [6]. All current assessments use one of the three genus level indices. Each index is described below and is used in each water region in this manner (see Figure 1A, index boundary map): Northwest Region, HGMI & CPMI; Northeast Region, HGMI; Raritan Region, HGMI & CPMI; Atlantic Region, CPMI & PMI; Lower Delaware Region, CPMI & PMI. The final index scores were derived in coordination with professional staff from Water Monitoring and Standards' Bureau of Freshwater and Biological Monitoring, Water Monitoring and Standards' Bureau of Water Quality Standards and Assessment, USEPA, United States Geological Survey (USGS), and the Delaware River Basin Commission (DRBC).

## High Gradient and Low Gradient Streams

Two of the indices (see Table 1) to be employed in New Jersey, the High Gradient Macroinvertebrate Index (**HGMI**) [11] and Coastal Plain Macroinvertebrate Index (**CPMI**) [12], were developed using guidelines outlined in USEPA *Rapid Bioassessment Protocols for Use in Wadeable Streams and Rivers* [6]. The resolution of index scoring thresholds was further enhanced by establishing a graphical relationship between the scores for each index and the tiers these scores represent in the context of a Biological Condition Gradient (BCG). The final index scoring thresholds serves to assess each site from two perspectives: the condition of the macroinvertebrate community and the regulatory use attainment.

For each index, four descriptive categories were established at break points along the statistical distribution of scores from reference to degraded conditions, coordinated to the BCG to increase the accuracy; "excellent", "good", "fair", and "poor" (see Table A1). "Excellent" and "good" fall into the acceptable regulatory range of fully attaining the aquatic life use. "fair" and "poor" fall below the acceptable regulatory range and are considered impaired, from a Federal Clean Water Act (CWA) perspective, and not attaining the use.

## Pinelands Streams

The Pinelands Macroinvertebrate Index (**PMI**) [13] was developed using the same USEPA guidelines and professional coordination as above. However, since a BCG was not developed, and not necessary from a regulatory standpoint, a graphical relationship between index scores and the BCG tiers was not generated. As with the high and low gradient indices, four descriptive categories were established at break points

along the statistical distribution of scores from reference to degraded conditions “excellent”, “good”, “fair”, and “poor” (see Table A1). For waters with a Surface Water Classification of “PL”, “excellent” and “good” are classified as reference or natural conditions of Pineland waters and fall into the acceptable regulatory range of fully attaining the aquatic life use. “Fair” and “poor” fall below the acceptable regulatory range of PL waters and are considered impaired, from a CWA perspective, and not attaining the use.

The unique chemical, physical, and biological properties characteristic of waters contained with the Pinelands area are also present for varying distances outside this jurisdictional delineation. To assess these Pinelands-like waters outside the Pinelands boundary, the Department delineated a 5 kilometer buffer around the Pinelands Area and will apply the PMI to this region. Pinelands-like waters outside the jurisdictional delineation, however, have a Surface Water Classification of FW2 and not PL. From a regulatory standpoint FW2 waters are held to a somewhat lower level of biological expectation than the Outstanding National Resource Waters (ONRW) waters contained within the PL designated area. Because of this lower regulatory expectation for FW2 waters, the PMI category of “fair” and above will be regarded as fully attaining the aquatic life use, i.e. biologically *nonimpaired* from a regulatory perspective. FW2 waters in this buffer region assessed as “poor” will be regarded as *impaired* and not supporting the aquatic life use.

**Table A1: Descriptive and regulatory thresholds for Fresh Water High Gradient (Highlands, Ridge and Valley, Piedmont), Low Gradient (Coastal Plain, Excluding Pinelands Waters) and Pinelands Waters.**

<b>High Gradient Macroinvertebrate Index (HGMI)</b> (Highlands, Ridge and Valley, Piedmont)		
<b>Assessment category</b>	<b>Index Score</b>	<b>Regulatory Threshold</b>

## **Trend Analysis**

In evaluating the current AMNET data against that of the previous round, a significant improvement or decline is considered to have occurred if the difference in AMNET scores have changed the bioassessment rating. A complete list of site-by-site comparisons is presented in Table 2, Volume 2 where a (+) indicates a significant improvement, a (–) indicates a significant decline, and a (/) indicates no change in rating. If a site was only sampled once in concurrent rounds, the change will have "nd" meaning there was "no data" available for a comparison.

## **SUPPLEMENTAL ANALYSES / EVALUATION METHODS**

### **Morphological Abnormalities**

Occasionally, morphological abnormalities have been found in individual macroinvertebrates recovered in WM&S/BFBM's AMNET collections. These deformities have been most readily detected in the Chironomidae (midges), where they occur primarily in the head appendages (antennae) and mouth parts (mentum and mandibles). While the incidence has been most frequent in the chironomids (especially those species categorized as detritivores, herbivores or periphyton feeders), abnormalities have also been observed in individuals of other taxonomic groups. Although this is not a factor in the data analysis, such features are noted as they may signify possible contaminants or stressful conditions in the respective drainages.

Abnormalities observed in the course of identification are noted; these results are summarized by sample site in Table 3, Volume 2. For Chironomidae, the data are displayed as # of chironomids with abnormalities / # of chironomids examined. For all other taxa, just the number of individuals with abnormalities is presented. Photographic examples of abnormalities in midge larvae and amphipods (scuds) are presented in Appendix B, Volume 2.

### **Habitat Assessment**

The physical attributes of habitat play an integral role in the health of the macroinvertebrate community. Where stations are physically comparable, differences in impairment can be attributed to water quality factors; however, physical habitat degradation alone can account for biological impairment in a stream [1]. Parameters evaluated include in-stream substrate, channel morphology, bank structural features, and riparian vegetation. The area evaluated includes the sample site and its immediate surroundings, particularly upstream, usually within a 100 – 200 foot radius. The visual-based qualitative habitat assessment results in one of four condition categories: optimal, suboptimal, marginal or poor, as outlined in the revised USEPA criteria [6].

The habitat assessment is separated into two basic approaches; one designed for high gradient streams and one designed for low gradient streams [6]. Examples of assessment forms for each approach can be found in Appendix C, Volume 2. Streams in the northern regions of New Jersey are generally considered to be "high gradient" streams, having substrates of rock and cobble of various sizes, and with relatively swift flow. Those in the Coastal Plain and Pinelands regions of southern New Jersey are considered as "low gradient" streams, having slower flow and more homogeneous substrates, primarily of sand or gravel and finer sediments. Habitat assessments may be temporarily downgraded by adverse weather conditions, such as excessive rainfall or prolonged drought. It should also be noted that habitat assessments are performed independently of the macroinvertebrate community analysis; thus, they do not factor into the final impairment score, but are used primarily as supplementary information.

## **Chemical Monitoring**

The Bureau of Freshwater and Biological Monitoring (BFBM) has various chemical monitoring networks throughout the State. These networks emphasize emerging state and federal strategies to more realistically assess the success of State and Federal Clean Water Act Programs. The sampling stations include surfacewater as well as groundwater monitoring.

Chemical data and results from these networks are integrated with results from the BFBM's biological networks, such as AMNET, for water quality assessments reported through the New Jersey Integrated Water Quality Monitoring and Assessment Report (Integrated Report).

The Bureau of Water Quality Standards and Assessment (BWQSA) is responsible preparing the biennial Integrated Report and coordinating water quality assessments of all waters of the State, including assessment of data collected by non-departmental entities (e.g., regional and local government agencies and volunteer monitoring organizations). BWQSA is also responsible for the development, adoption, and administration of New Jersey's Surface Water Quality Standards and Ground Water Quality Standards.

The federal Clean Water Act mandates that states submit biennial reports to USEPA describing the quality of their waters. The biennial "Statewide Water Quality Inventory Report" or "305(b) Report" must include the status of principal waters in terms of overall water quality and support of designated uses, as well as strategies to maintain and improve water quality. The 305(b) reports are used by Congress and USEPA to establish program priorities and funding for federal and state water resource management programs. This report is also referred to as the "Integrated List of Waters" (Integrated List). The biennial List of Water Quality Limited Waters or "303(d) List" identifies waters that are not attaining designated uses because they do not meet surface water quality standards despite the implementation of technology-based effluent limits. States must prioritize waters on the 303(d) List of Water Quality Limited Waters for Total Maximum Daily Load (TMDL) development and identify those high priority waters for which they anticipate establishing TMDLs in the next two years.

The New Jersey Integrated Water Quality Monitoring and Assessment Reports (Integrated Reports) are intended to provide effective tools for maintaining high quality waters and improving the quality of waters that do not attain their designated uses. The Integrated Reports describe attainment of the designated uses specified in New Jersey's Surface Water Quality Standards (N.J.A.C. 7:9B), which include: aquatic life; recreation; drinking, industrial, and agricultural water supply; fish consumption; and shellfish harvest for consumption.

The Integrated Report process begins with the solicitation of water quality-related data to support the development of the 303(d) List. The Department then updates the Integrated Water Quality Monitoring and Assessment Methods Document (Methods Document), as needed. This document includes a description of quality assurance and other data requirements, as well as the scientific methods to be used to assess water quality and use support. The Methods Document also explains the rationale for placing waters on the 303(d) List, delisting waters from the 303(d) List, and ranking the priority of 303(d)-Listed waters for TMDL development. A notice of availability for public review of the draft Methods Document is published in the New Jersey Register and a thirty-day comment period is provided. After review and consideration of comments received on the proposed Methods Document, the Department finalizes the Methods Document and publishes it on the Department's Web site along with the agency responses to public comments received.

After the Methods Document is finalized, the Department compiles all readily available data that meets quality requirements and assesses the data to determine designated use support and compliance with surface water quality standards. The results of these assessments are presented in the Integrated List and the 303(d) List. The Department prepares these Lists as part of the Integrated Report, along with a

discussion of the assessment results, water quality trends, other water quality assessments, descriptions of water quality programs and actions taken and planned to restore water quality, including TMDL schedules, as well as monitoring needs and schedules, and makes it available for public review. The draft 303(d) List is submitted to USEPA for approval along with the two-year TMDL schedule and priority ranking.

The Department will attempt to identify the potential sources of impairment using the Stressor Identification (SI) process. The purpose of the Stressor Identification (SI) process is to identify the principle stressor(s), including but not limited to specific pollutants, responsible for the degraded biological condition. Identifying whether the principal stressor(s) is a *pollutant*\* or due to more generic landscape changes caused by human activities, is the first step towards deciding whether a pollutant(s) specific TMDL or other appropriate management measures will be taken to remediate the impairment. At present, no sites have been targeted in this Region for the SI process.

## RESULTS AND DISCUSSION

### Summary of Statewide AMNET Data

The current study marks the fourth round of sampling for the Upper Delaware/Northwest Region AMNET study. For the purpose of comparing Rounds, Round 3 results were re-assessed using the new indices. The Upper Delaware/Northwest Region has shown considerable changes since the previous rounds by virtue of using the more geographically specific assessment. The number of “excellent” and “good” sites has shown a slight increase, while the number of “fair” and “poor” sites has shown a slight decline. The table below presents the proportions of “excellent”, “good”, “fair”, and “poor” AMNET sites for all New Jersey Water Regions in the third AMNET round, plus the fourth round for the Upper Delaware/Northwest Water Region.

Region	Number of sites				
	Excellent	Good	Fair	Poor	Total sites
<b>Fourth round</b>					
Upper Delaware	41 (29.7%)	49 (35.5%)	39 (28.3%)	9 (6.5%)	138
<b>Third round</b>					
Upper Delaware	33 (23.4%)	48 (34.0%)	43 (30.5%)	17 (12.1%)	141
Northeast	8 (7.8%)	13 (12.7%)	56 (54.9%)	25 (24.5%)	102
Raritan	27 (20.8%)	38 (29.2%)	64 (40.0%)	31 (23.8%)	160
Atlantic	53 (27.0%)	44 (22.4%)	77 (39.3%)	22 (11.2%)	196
Lower Delaware	13 (8.1%)	35 (21.9%)	80 (50.0%)	32 (20.0%)	160

\* As defined in the N.J. Water Pollution Control Act (N.J.S.A. 58:10A-1 et seq.) and the Federal Water Pollution Control Act, aka “Clean Water Act” (33 U.S.C. 1251-1376)

## Results and Trends

Overall, the bioassessment ratings for each of the monitoring stations are best estimates of the in-stream biological impairment based upon the data obtained in the current AMNET survey. Detailed taxonomic and statistical data, bioassessment ratings, habitat assessment scores and observations for each AMNET site are given in Table 2 and Appendix D, Volume 2.

Figure 5 depicts the overall results for the Round 4 study in the Upper Delaware/Northwest Water Region. Of the 138 monitoring stations sampled during this study period, 41 (29.7%) were found “excellent”, 49 (35.5%) “good”, 39 (28.3%) “fair”, and 9 (6.5%) “poor” (see Table 2, Volume 2).

Figure 5

Figure 6

Figure 6 shows the results obtained from 141 AMNET sites within the Upper Delaware/Northwest Water Region that were sampled during the previous (Round 3) Upper Delaware/Northwest study (see “Site Selection” p.6 & Table 2, Volume 2). While the results for Round 4 were similar to those for Round 3, for the current sampling period the numbers of “good” sites were slightly higher, and the number of “excellent”, “fair”, and “poor” sites were slightly lower. [4].

Figure 7 displays the percentage of change in rating among the same 138 AMNET sites in the Upper Delaware/Northwest Water Region that were sampled during the third round study period [4], and again during the current (Round 4) study period (see “Site Selection” & Table 2, Volume 2). The green indicates sites that have undergone a positive change, yellow indicates no change, and red indicates a negative change. Positive change is defined as an improved rating from the previous Round’s rating, while a negative change is defined as a downgraded rating from the previous Round (see Table 2, Volume 2).

Percent Change in Rating Between the Round 3 and the Round 4 Monitoring (138 sites total)

Figure 7

## Regional Results

A USGS study, using data generated from NJDEP's AMNET program [15], statistically related levels of impairment to physiographic land types, corresponding land uses, and other anthropogenic factors on a statewide scale. A non-impaired community was most positively related to the area of forested and undeveloped land in its watershed upstream, and to the total underlying terrain in the steeper gradient ecoregions of northwestern New Jersey (i.e. Reading Prong/Highlands). Conversely, an impaired community was most positively related to the area of urban land, and to the total volume of wastewater (point source) discharge [15]. The table below presents the proportion of “excellent”, “good”, “fair”, and “poor” AMNET sites, based on the current data, in each of the Upper Delaware/Northwest Watershed Management Areas.

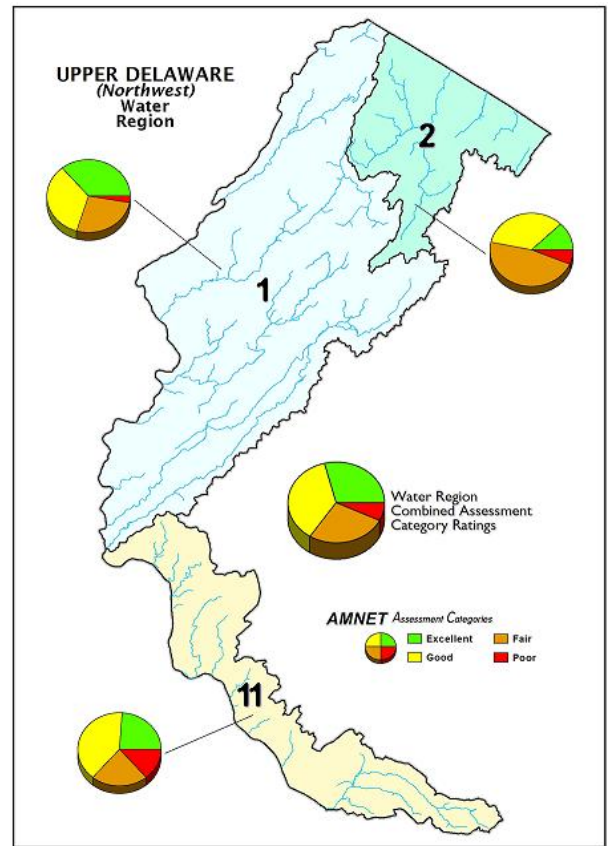

Figure 8

WMA	Sub-basins	Excellent	Good	Fair	Poor	Total sites
1	Upper Delaware River tributaries	28 (37.3%)	25 (33.3%)	20 (26.7%)	2 (2.7%)	75
2	Upper Wallkill River system	2 (11.8%)	6 (35.3%)	8 (47.1%)	1 (5.9%)	17
11	Central Delaware River tributaries	11 (23.9%)	18 (39.1%)	11 (23.9%)	6 (13.0%)	46
<b>Totals:</b>		41 (29.7%)	49 (35.5%)	39 (28.3%)	9 (6.5%)	138

Figure 8 illustrates the proportions of “excellent”, “good”, “fair”, and “poor” sites in each WMA of the Upper Delaware/Northwest Water Region for the current AMNET round.

## Evaluation by WMA

**Watershed Management Area #1** includes a total of 75 AMNET sites in the Shimmers Brook, Flat Brook, Vancampens Brook, Papakating Creek, Delawanna Creek, Pohatcong Creek, Lopatcong Creek, Pequest River, Paulins Kill, Clove Brook, and Musconetcong River watersheds, in Hunterdon, Sussex, Morris and Warren Counties (see Maps 2, 3, 4, & 5, Volume 2). Three sites were not sampled. AN0001 due to lack of

flow, AN0020 due to a collection error, and AN0031 inaccessible because of bridge construction. Figure 9 shows the current site rating summaries for WMA #1 with 37.3% (28 sites) “excellent”, 33.3% (25 sites) “good”, 26.7% (20 sites) “fair”, and 2.7% (2 sites) “poor”. Figure 10 depicts the results obtained from 78 sites sampled during the earlier (Round 3) survey [4]. Comparing the current results to the earlier results, a significant improvement is seen at 31 sites and a significant decline at 12 sites (see Table 2, Volume 2). The number of “excellent” and “fair” sites is slightly higher than the earlier data, and the number of “poor” and “good” sites have declined. The majority (68.0%) of habitat scores are in the suboptimal range, with 30.7% receiving an optimal score and 1.3% receiving a marginal score. Abnormalities in chironomid larvae and other invertebrate families were found at eight sites (one each on Culvers Ck, UNT to Pequest River, Bear Ck, Pequest River, Pophandusing Bk, Lopatcong Ck, Pohatcong Ck, and Hances Bk) (see Maps 2, 3, 4, & 5, Table 3, Volume 2). One of these sites (AN0053) displayed chronic abnormalities (see Table 3, Volume 2). The table below presents a synopsis of AMNET data for WMA #1; AMNET site locations and bioassessment ratings within WMA #1 are shown in Figure 11.

flow, AN0020 due to a collection error, and AN0031 inaccessible because of bridge construction. Figure 9 shows the current site rating summaries for WMA #1 with 37.3% (28 sites) “excellent”, 33.3% (25 sites) “good”, 26.7% (20 sites) “fair”, and 2.7% (2 sites) “poor”. Figure 10 depicts the results obtained from 78 sites sampled

Poor	8	10.3%	2	2.7%	Poor	---	---
<b>Total sites</b>	78		75			75	

**Watershed Management Area #2** includes a total of 17 AMNET sites in the Beaver Run, Black Ck, Clove Bk, Papakating Ck, Wallkill River, and Wawayanda Ck watersheds, in Sussex County (see Map 8, Volume 2). Figure 12 shows the current site rating summaries for WMA # 2: 11.8% (2 sites) “excellent”, 35.3% (6 sites) “good”, 47.1% (8 sites) “fair”, and 5.9% (1 site) “poor”. Figure 13 depicts the results obtained from 17 sites sampled during the earlier (Round 3) survey [4]. Comparing the current (Round 4) results to the earlier (Round 3) results, a significant improvement is apparent at four sites while five sites exhibited

a decline in impairment rating (see Table 2, Volume 2). The number of “excellent” sites decreased slightly, while the number of “good” sites increased slightly, since the earlier sampling, with the number of “fair” and “poor” sites remaining the same (see Table 2, Volume 2). The majority (58.8%) of habitat scores are in the suboptimal range with 29.4% receiving an optimal and 11.8% receiving a marginal score. Abnormalities in chironomid larvae and other invertebrate families were found at one site (Papakating Ck) (Maps 6 & 7, Table 3, Volume 2). This site did not display chronic abnormalities (see Table 3, Volume 2). The table below presents a synopsis of AMNET data for WMA #2; AMNET site locations and bioassessment ratings within WMA #2 are shown in Figure 14.

**Figure 14**

**WMA # 2 Combined Results Table**

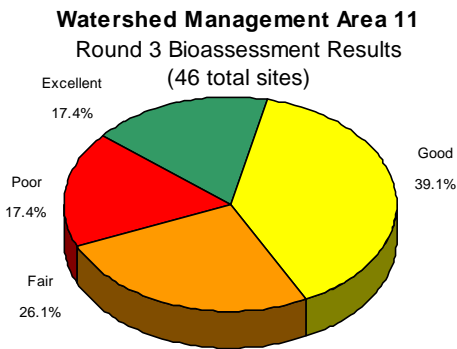

Bio Rating	Round 3		Round 4		Habitat Assessment	Round 4	
Excellent	3	17.6%	2	11.8%	Optimal	5	29.4%
Good	5	29.4%	6	35.3%	Suboptimal	10	58.8%
Fair	8	47.1%	8	47.1%	Marginal	2	11.8%
Poor	1	5.9%	1	5.9%	Poor	---	---
<b>Total sites</b>	17		17			17	

**Watershed Management Area #11** includes a total of 46 AMNET sites in the Alexauken Ck, Assunpink Ck, Hakhokake Ck, Jacobs Ck, Lockatong Ck, Miry Run, Moores Ck, Nishisakawick Ck, Plum Brook, Shabakunk Ck, Swan Ck, Warford Ck, Wickecheoke Ck, and Woolseys Bk watersheds, in Hunterdon, Mercer, and Monmouth Counties (see Maps 6 & 7, Volume 2). Figure 15 shows the current site rating summaries for WMA # 11: 23.9% (11 sites) “excellent”, 39.1% (18 sites) “good”, 23.9% (11 sites) “fair”, and 13.0% (6 sites) “poor”. Figure 16 depicts the results obtained from 46 sites sampled during the earlier (Round 3) survey [4]. Comparing the current to the earlier results, a significant improvement is seen at 16 sites, and a significant decline, at 7 sites (see Table 2, Volume 2). The number of “excellent” sites increased slightly from that of the earlier sampling, and the number “fair” and “poor” sites is slightly decreased, with the number of “good” sites remaining the same (see Table 2, Volume 2). The majority of sites (76.1%) received an suboptimal habitat score, with 15.2% receiving an optimal score and 8.7% receiving a marginal score. Abnormalities in chironomid larvae and other invertebrate families were found at six sites (one each on Harihokake Ck, Wickecheoke Ck, Swan Ck, UNT to Shipetaukin Ck, Shabakunk Ck, and Miry Run) (see Map 8, Table 3, Volume 2). None of these sites displayed chronic abnormalities (see Table 3, Volume 2). The table below presents a synopsis of AMNET data for WMA #11; AMNET site locations and bioassessment ratings within WMA # 11 are shown in Figure 17.

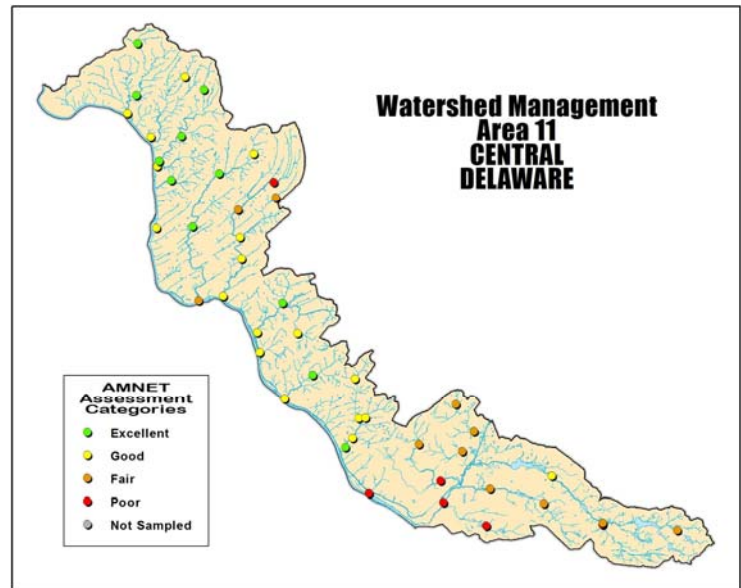

**Figure 15**

## Macroinvertebrate Abnormalities

Occasionally, morphological abnormalities have been found in individual macroinvertebrates recovered in WM&S/BFBM's AMNET collections. These deformities have been most often detected in larval organisms belonging to the insect family Chironomidae (midges), where they occur primarily in the head appendages (antennae) and mouthparts (mentum and mandibles). Abnormalities have also been observed in individuals of other taxonomic groups (such as Amphipoda), but they are most often noted in the mouthparts and antennae of Chironomidae because these features are key characteristics used in identification. Chironomidae larvae often comprise a large component of the benthic community of a stream or river, particularly in those affected by human disturbances, and they are part of the diet of predatory invertebrates and fish. As a result, chironomids are an important transfer vector linking the movement of contaminants from sediments to higher trophic levels [16].

Hamilton and Saether [17] noted deformed specimens (Chironomidae) occurred in areas of industrial or agricultural chemical input, but not in areas receiving only domestic effluents. Subsequent studies have supported this finding. But the presence of deformed organisms in a sample is difficult to interpret. Not all genera appear to react to the presence of contaminants in the same manner [18]. Most of the research has been focused on a few genera. The North Carolina Division of Environmental Management [19] has developed an index to evaluate deformities, using the frequency and severity of deformities observed in Chironomidae larvae of just the genus *Chironomus*. Secondly, morphological deformities undoubtedly occur in Chironomidae larvae living in uncontaminated environments. Even robust, healthy populations of any fauna are likely to include a certain proportion of physiologically weaker individuals which, for various reasons, may be more prone or genetically predisposed to malformation [18]. With a lack of baseline data of deformities in more pristine environments, the level at which these deformities becomes significant is somewhat uncertain. Currently, although not an indicator of specific contaminants, the occurrence of abnormal chironomid larvae can serve as an economical and long-term monitor of the benthic environment, and can suggest where more intensive bioassays and chemical testing would be most effectively employed [20].

Bearing in mind that the primary focus of the AMNET sampling is not to find morphological abnormalities, a listing of all AMNET sites in the Upper Delaware/Northwest Water Region exhibiting these deformities is presented in Table 3, Volume 2. The data are displayed as # of chironomids with abnormalities/# of chironomids examined. For all other taxa, just the number of individuals with abnormalities is presented. The significance of these abnormalities has not been statistically evaluated. Deformities are called "chronic" if they were observed in more than one round of sampling at a given site. Also, the presence of abnormalities is not factored into the index scoring, but used to identify sites where additional investigations are needed.

A slight decrease in the number of abnormalities are seen in the current sampling as compared to the previous (Round 3) sampling [4]. From the current sampling of 138 sites, 15 (10.9%) contained organisms with abnormalities (Maps 2 - 8 , Volume 2). Only one of the sites (AN0053) exhibited a "chronic" presence of abnormalities (Table 3, Volume 2). Further study is needed to establish the significance of the presence of abnormalities.

## **Causes of Biological Impairment**

Biological impairment, as determined through RBP analysis, is manifested by alterations or differences in macroinvertebrate community structure, compared to a reference or "ideal" condition. Although bioassessments are useful for identifying biological impairments, they do not identify the cause or causes of impairments. Linking biological effects with their causes is particularly complex when multiple stressors impact a waterbody[22]. A more intensive Stressor Identification (SI) study is necessary in order to pinpoint the probable cause or causes of the observed biological impairment.

Some common candidate causes which frequently appear on the USEPA's 303(d) list of impaired waterbodies include[23]:

- Metals
- Sediments
- Nutrients
- Dissolved Oxygen
- Temperature
- Ionic Strength
- Flow Alteration
- Unspecified Toxic Chemicals

## **Habitat Assessment vs. Biological Assessment**

Generally, there is a correlation between habitat and biological impairment. However, definitive correlations can only be determined on a site specific basis. When assessing habitat degradation on an individual site, often the data suggests that other factors, which may include land use and/or water quality, are likely contributing to the observed biological assessments. Due to the prevalence of multiple stressors in areas of complex land use, sites with a "fair" or "poor" biological assessment, but with a relatively high habitat assessment score, could be impacted by point and/or nonpoint sources outside the range of the visual based habitat assessment. Also, an intermittent or short term impact may have occurred which left no obvious visual evidence at the site. In these cases, further investigation is needed to determine the source of impairment that is affecting the biota. Some sites assessed with an "excellent" or "good" biological assessment may have a relatively degraded habitat assessment. This could be due to a temporary degradation, such as drought or flooding (near to the time of the assessment), which was not severe enough to effect the biota. It is also possible that a temporary or recent degradation may not have immediate observable effects on the biota. In either case these sites should be studied further to avoid future impairment to the biota.

As reflected in the present study results, human land uses and practices, superimposed on the undisturbed physical terrain, play a major role in controlling the degree of pollution or degradation in a stream system [15]. The relationship between benthic macroinvertebrate community impairment has been statistically related to different physiographic land types, land uses and other anthropogenic factors, on a statewide basis [15]. These findings strongly indicate that human land uses and practices play a major role in the degree of pollution or degradation in a stream system. Data analysis from Ayers et al., 2000 [21] for instance, concludes the following:

1. Fish and invertebrate communities are commonly impaired in urban streams;
2. Invertebrate community impairment was related to total urban land and total wastewater flow upstream of a site;

3. Changes in aquatic community structure were statistically related to environmental variables along the urban gradient – that is to say that such things as impervious surfaces were related to a negative response in the aquatic invertebrate community.

Conversely, the same Ayers data analysis also demonstrated that the area of forest and wetland in a stream's drainage basin was a strong mitigating factor in protecting invertebrate community health.

### **Additional Information**

Additional Information on the AMNET program can be obtained from the WM&S' Bureau of Freshwater & Biological Monitoring by calling 609-292-0427 or visiting its website at: <http://www.state.nj.us/dep/wms/bfbm>

Raw data is posted on this website by the end of the calendar year that the data is received and validated. GIS shapefiles will also be available on the NJDEP web site once all data is reviewed and finalized.

Additionally, raw data is submitted to WQX as soon as the data is received and validated. WQX is USEPA's repository and framework for water quality, biological, and physical data. It is used by state environmental agencies, EPA and other federal agencies, universities, private citizens, and many others to store data. The retrieval of the data is handled through the STORET interface and can be accessed at: <http://www.epa.gov/storet>

Comments are welcome and may be emailed to: [bfbm@dep.state.nj.us](mailto:bfbm@dep.state.nj.us).

# Table 1

## Coastal Plain Macroinvertebrate Index (CPMI)<sup>1</sup>

Study area: southern New Jersey, below the geologic fall-line; Middle Atlantic Coastal Plain ecoregion, excluding the Pinelands National Reserve. See figure A1.

### Index Metrics

1. Total number of genera
2. Total number of EPT genera
3. Percent Ephemeroptera genera
4. Hilsenhoff Biotic Index
5. Percent Clinger genera

Index Metric	Score			
	6	4	2	0
Number of genera	>25	17-25	9-16	<9
Number of EPT genera	>9	7-9	4-6	<4
% of Ephemeroptera	>29	20-29	10-19	<10
Hilsenhoff Biotic Index	<4.9	4.9-6.0	6.1-7.3	>7.3
% Clingers	>51	34-51	17-33	<17

Assessment Rating	Score
Excellent	22-30
Good	12-20
Fair	10-6
Poor	< 6

### Reference

J.R. Maxted, et al. Assessment framework for mid-Atlantic coastal plain streams using benthic macroinvertebrates. J.N. Am. Benthol. Soc. 2000, 19(1):128-144.

### Attributes

**Excellent: Minimal changes in structure of biological community and minimal changes in ecosystem function.** Virtually all native taxa are maintained with some changes to biomass and/or abundance; ecosystem functions are fully maintained within the range of natural variability.

**Good: Some evident changes in structure of the biotic community and minimal changes in ecosystem function.** Some changes in structure due to loss of some rare native taxa; shifts in relative abundance of taxa but sensitive-ubiquitous taxa are common and abundant; ecosystem functions are fully maintained.

**Fair: Moderate to major changes in structure of biological community and moderate changes in ecosystem function.** Sensitive taxa are markedly diminished; conspicuously unbalanced distribution of major groups from that expected; organism condition shows signs of physiological stress; system function shows reduced complexity.

**Poor: Extreme changes in structure of biological community and major loss of ecosystem function.** Extreme changes in structure; wholesale changes in taxonomic composition; extreme alterations from normal densities and distributions; organism condition is often poor; ecosystem functions are severely altered.

<sup>1</sup> Based on 100 organism subsample, genus level taxonomy

## Table 1 (cont)

### Pinelands Macroinvertebrate Index (PMI)<sup>1</sup>

Study area: southern New Jersey, below the geologic fall-line within the Pinelands National Reserve and extending 5 kilometers outside the Reserve boundary. See figure A1.

#### Index Metrics

1. Number of Insect genera
2. Number of Non-insect genera
3. Percent Plecoptera (P) and Trichoptera (T)
4. Percent Diptera genera excluding Tanytarsini
5. Percent Mollusca and Amphipoda
6. Beck's Biotic Index
7. Percent Filterers

<u>Assessment Rating</u>	<u>Score</u>
Excellent	≥ 63
Good	< 63-56
Fair	< 56-34
Poor	< 34

#### Reference

Benjamin Jessup, et al. Report. Development of the New Jersey Pinelands macroinvertebrate index (PMI). TetraTech, Inc. Owings Mills, MD. March, 2005.

#### *Attributes*

**Excellent: Minimal changes in structure of biological community and minimal changes in ecosystem function.** Virtually all native taxa are maintained with some changes to biomass and/or abundance; ecosystem functions are fully maintained within the range of natural variability.

**Good: Some evident changes in structure of the biotic community and minimal changes in ecosystem function.** Some changes in structure due to loss of some rare native taxa; shifts in relative abundance of taxa but sensitive-ubiquitous taxa are common and abundant; ecosystem functions are fully maintained.

**Fair: Moderate to major changes in structure of biological community and moderate changes in ecosystem function.** Sensitive taxa are markedly diminished; conspicuously unbalanced distribution of major groups from that expected; organism condition shows signs of physiological stress; system function shows reduced complexity.

**Poor: Extreme changes in structure of biological community and major loss of ecosystem function.** Extreme changes in structure; wholesale changes in taxonomic composition; extreme alterations from normal densities and distributions; organism condition is often poor; ecosystem functions are severely altered.

<sup>1</sup> Based on 100 organism subsample, genus level taxonomy

## Table 1 (cont)

### High Gradient Macroinvertebrate Index (HGMI)<sup>1</sup>

Study area: northern New Jersey, above the geologic fall-line including the following ecoregions: North Central Appalachians, Central Appalachian Ridges and Valleys, Northeastern Highlands, Northeastern Coastal Zone, and Northern Piedmont. See figure A1.

#### Index Metrics

1. Total number of genera<sub>adj</sub> =  $26.53 + \text{Metric} - [22.776 + 4.173 * \log_{10}(\text{areasqkm})]$
2. Percent of genera that are not insects
3. Percent sensitive EPT (excluding Hydropyschidae, including Dipletrona)<sub>adj</sub>  
=  $37.49 + \text{Metric} - [49.922 - 13.800 * \log_{10}(\text{areasqkm})]$
4. Number of scraper genera<sub>adj</sub> =  $5.44 + \text{Metric} - [3.889 + 1.724 * \log_{10}(\text{areasqkm})]$
5. Hilsenhoff Biotic Index<sub>adj</sub> =  $4.23 + \text{Metric} - [3.407 + 0.918 * \log_{10}(\text{areasqkm})]$
6. Number of New Jersey TALU attribute 2 genera
7. Number of New Jersey TALU attribute 3 genera

ADJ (Adjusted metric value) =  $\text{Mean}_{\text{reference}} + \text{Metric}_{\text{observed}} - \text{Metric}_{\text{predicted}}$ , where predictions are based on linear regression analysis of reference metric values on catchment size.

<u>Assessment Rating</u>	<u>Score</u>
Excellent	$\geq 63$
Good	$< 63 - 42$
Fair	$< 42 - 21$
Poor	$< 21$

NOTES:

# chironomids with deformities / # chironomids examined

+ — indicates the number of non-chironomids having abnormalities

abnormalities are considered chronic if they appear in both the Round 3 and the Round 4 columns

Table 4 — HABITAT ASSESSMENT FOR HIGH GRADIENT STREAMS

Habitat Parameter	Condition Category			
	Optimal	Suboptimal	Marginal	Poor
<b>1. Epifaunal Substrate/Available Cover</b>	Greater than 70% of substrate favorable for epifaunal colonization and fish cover; mix of snags, submerged logs, undercut banks, cobble or other stable habitat and at stage to allow full colonization potential (i.e., logs/snags that are <u>not</u> new fall and <u>not</u> transient).	40-70% mix of stable habitat; well suited for full colonization potential; adequate habitat for maintenance of populations; presence of additional substrate in the form of newfall, but not yet prepared for colonization (may rate at high end of scale).	20-40% mix of stable habitat; habitat availability less than desirable; substrate frequently disturbed or removed.	Less than 20% stable habitat; lack of habitat is obvious; substrate unstable or lacking.
<b>SCORE</b>	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>2. Embeddedness</b>	Gravel, cobble, and boulder particles are 0-25% surrounded by fine sediment.	Gravel, cobble, and boulder particles are 25-50% surrounded by fine sediment.	Gravel, cobble, and boulder particles are 50-75% surrounded by fine sediment.	Gravel, cobble, and boulder particles are more than 75% surrounded by fine sediment.
<b>SCORE</b>	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>3. Velocity/Depth Regimes</b>	All 4 velocity/depth regimes present (slow-deep, slow-shallow, fast-deep, fast-shallow). (slow is <0.3 m/s, deep is >0.5 m)	Only 3 of the 4 regimes present (if fast-shallow is missing, score lower than if missing other regimes).	Only 2 of the 4 habitat regimes present (if fast-shallow or slow-shallow are missing, score low).	Dominated by 1 velocity / depth regime (usually slow-deep).
<b>SCORE</b>	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>4. Sediment Deposition</b>	Little or no enlargement of islands or point bars and less than 5% (<20% for low-gradient streams) of the bottom affected by sediment deposition.	Some new increase in bar formation, mostly from gravel, sand or fine sediment; 5-30% (20-50% for low-gradient) of the bottom affected; slight deposition in pools.	Moderate deposition of new gravel, sand or fine sediment on old and new bars; 30-50% (50-80% for low-gradient) of the bottom affected; sediment deposits at obstructions, constrictions, and bends; moderate deposition of pools prevalent.	Heavy deposits of fine material, increased bar development; more than 50% (80% for low-gradient) of the bottom changing frequently; pools almost absent due to substantial sediment deposition.
<b>SCORE</b>	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>5. Channel Flow Status</b>	Water reaches base of both lower banks, and minimal amount of channel substrate is exposed.	Water fills >75% of the available channel; or <25% of channel substrate is exposed.	Water fills 25-75% of the available channel, and/or riffle substrates are mostly exposed.	Very little water in channel and mostly present as standing pools.
<b>SCORE</b>	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>6. Channel Alteration</b>	Channelization or dredging absent or minimal; stream with normal pattern.	Some channelization present, usually in areas of bridge abutments; evidence of past channelization, i.e., dredging, (greater than past 20 yrs.) may be present, but recent channelization is not present.	Channelization may be extensive; embankments or shoring structures present on both banks; and 40 to 80% of stream reach channelized and disrupted.	Banks shored with gabion or cement; over 80% of the stream reach channelized and disrupted. In stream habitat greatly altered or removed entirely.
<b>SCORE</b>	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>7. Frequency of Riffles (or bends)</b>	Occurrence of riffles relatively frequent; ratio of distance between riffles divided by width of the stream <7:1 (generally 5 to 7); variety of habitat is key. In streams where riffles are continuous, placement of boulders or other large, natural obstruction is important.	Occurrence of riffles infrequent; distance between riffles divided by the width of the stream is between 7 to 15.	Occasional riffle or bend; bottom contours provide some habitat; distance between riffles divided by the width of the stream is between 15 to 25.	Generally all flat water or shallow riffles; poor habitat; distance between riffles divided by the width of the stream is a ratio of >25.
<b>SCORE</b>	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>8. Bank Stability (score each bank)</b> Note: determine left or right side by facing downstream.	Banks stable; evidence of erosion or bank failure absent or minimal; little potential for future problems. <5% of bank affected.	Moderately stable; infrequent, small areas of erosion mostly healed over. 5-30% of bank in reach has areas of erosion.	Moderately unstable; 30-60% of bank in reach has areas of erosion; high erosion potential during floods.	Unstable; many eroded areas; "raw" areas frequent along straight sections and bends; obvious bank sloughing; 60-100% of bank has erosional scars.
SCORE ___ (LB)	Left Bank 10 9	8 7 6	5 4 3	2 1 0
SCORE ___ (RB)	Right Bank 10 9	8 7 6	5 4 3	2 1 0
<b>9. Bank Vegetative Protection (score each bank)</b>	More than 90% of the streambank surfaces and immediate riparian zone covered by native vegetation, including trees, under story shrubs, or nonwoody macrophytes; vegetative disruption through grazing or mowing minimal or not evident; almost all plants allowed to grow naturally.	70-90% of the streambank surfaces covered by native vegetation, but one class of plants is not well-represented; disruption evident but not affecting full plant growth potential to any great extent; more than one-half of the potential plant stubble height remaining.	50-70% of the streambank surfaces covered by vegetation; disruption obvious; patches of bare soil or closely cropped vegetation common; less than one-half of the potential plant stubble height remaining.	Less than 50% of the streambank surfaces covered by vegetation; disruption of streambank vegetation is very high; vegetation has been removed to 5 centimeters or less in average stubble height.
SCORE ___ (LB)	Left Bank 10 9	8 7 6	5 4 3	2 1 0
SCORE ___ (RB)	Right Bank 10 9	8 7 6	5 4 3	2 1 0
<b>10. Riparian Vegetative Zone Width (score each bank riparian zone)</b>	Width of riparian zone >18 meters; human activities (i.e., parking lots, roadbeds, clear-cuts, lawns, or crops) have not impacted zone.	Width of riparian zone 12-18 meters; human activities have impacted zone only minimally.	Width of riparian zone 6-12 meters; human activities have impacted zone a great deal.	Width of riparian zone <6 meters; little or no riparian vegetation due to human activities.
SCORE ___ (LB)	Left Bank 10 9	8 7 6	5 4 3	2 1 0
SCORE ___ (RB)	Right Bank 10 9	8 7 6	5 4 3	2 1 0

Table 4 (cont.) — HABITAT ASSESSMENT FOR LOW GRADIENT STREAMS

Habitat Parameter	Condition Category			
	Optimal	Suboptimal	Marginal	Poor
<b>1. Epifaunal Substrate/Available Cover</b>	Greater than 50% of substrate favorable for epifaunal colonization and fish cover; mix of snags, submerged logs, undercut banks, cobble or other stable habitat and at stage to allow full colonization potential (i.e., logs/snags that are <u>not</u> new fall and <u>not</u> transient).	30-50% mix of stable habitat; well suited for full colonization potential; adequate habitat for maintenance of populations; presence of additional substrate in the form of newfall, but not yet prepared for colonization (may rate at high end of scale).	10-30% mix of stable habitat; habitat availability less than desirable; substrate frequently disturbed or removed.	Less than 10% stable habitat; lack of habitat is obvious; substrate unstable or lacking.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>2. Pool Substrate Characterization</b>	Mixture of substrate materials, with gravel and firm sand prevalent; root mats and submerged vegetation common.	Mixture of soft sand, mud, or clay; mud may be dominant; some root mats and submerged vegetation present.	All mud or clay or sand bottom; little or no root mat; no submerged vegetation.	Hard-pan clay or bedrock; no root mat or vegetation.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>3. Pool Variability</b>	Even mix of large-shallow, large-deep, small-shallow, small-deep pools present.	Majority of pools large-deep; very few shallow.	Shallow pools much more prevalent than deep pools.	Majority of pools small-shallow or pools absent.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>4. Sediment Deposition</b>	Little or no enlargement of islands or point bars and less than 5% <20% for low-gradient streams) of the bottom affected by sediment deposition.	Some new increase in bar formation, mostly from gravel, sand or fine sediment; 5-30% (20-50% for low-gradient) of the bottom affected; slight deposition in pools.	Moderate deposition of new gravel, sand or fine sediment on old and new bars; 30-50% (50-80% for low-gradient) of the bottom affected; sediment deposits at obstructions, constrictions, and bends; moderate deposition of pools prevalent.	Heavy deposits of fine material, increased bar development; more than 50% (80% for low-gradient) of the bottom changing frequently; pools almost absent due to substantial sediment deposition.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>5. Channel Flow Status</b>	Water reaches base of both lower banks, and minimal amount of channel substrate is exposed.	Water fills >75% of the available channel; or <25% of channel substrate is exposed.	Water fills 25-75% of the available channel, and/or riffle substrates are mostly exposed.	Very little water in channel and mostly present as standing pools.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>6. Channel Alteration</b>	Channelization or dredging absent or minimal; stream with normal pattern.	Some channelization present, usually in areas of bridge abutments; evidence of past channelization, i.e., dredging, (greater than past 20 yrs.) may be present, but recent channelization is not present.	Channelization may be extensive; embankments or shoring structures present on both banks; and 40 to 80% of stream reach channelized and disrupted.	Banks shored with gabion or cement; over 80% of the stream reach channelized and disrupted. In stream habitat greatly altered or removed entirely.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>7. Channel Sinuosity</b>	The bends in the stream increase the stream length 3 to 4 times longer than if it was in a straight line. (Note - channel braiding is considered normal in coastal plains and other low-lying areas. This parameter is not easily rated in these areas.	The bends in the stream increase the stream length 2 to 3 times longer than if it was in a straight line.	The bends in the stream increase the stream length 2 to 1 times longer than if it was in a straight line.	Channel straight; waterway has been channelized for a long distance.
SCORE	20 19 18 17 16	15 14 13 12 11	10 9 8 7 6	5 4 3 2 1 0
<b>8. Bank Stability (score each bank)</b>	Banks stable; evidence of erosion or bank failure absent or minimal; little potential for future problems. <5% of bank affected.	Moderately stable; infrequent, small areas of erosion mostly healed over. 5-30% of bank in reach has areas of erosion.	Moderately unstable; 30-60% of bank in reach has areas of erosion; high erosion potential during floods.	Unstable; many eroded areas; "raw" areas frequent along straight sections and bends; obvious bank sloughing; 60-100% of bank has erosional scars.

# APPENDIX D

## Taxonomic and Statistical Data, Biological Assessments, Habitat Assessment Scores and Observations from the Round 4 Northwest Water Region AMNET Study (Site numbers, locations, sample dates, and USGS topographic quadrangle, top of page.)

### Notes/Definitions:

Statistical data includes those biometric results that are applied to the following ratings.

<b>CPMI</b>	<b>PMI</b>	<b>HGMI</b>
<ol style="list-style-type: none"> <li>1. Total # of Taxa</li> <li>2. # of EPT taxa</li> <li>3. % Ephemeroptera</li> <li>4. Hilsenhoff Biotic Index (HBI)</li> <li>5. % clingers</li> </ol>	<ol style="list-style-type: none"> <li>1. Insect taxa</li> <li>2. Non-insect taxa</li> <li>3. % Plecoptera + Trichoptera</li> <li>4. % Diptera excluding Tanytarsini</li> <li>5. % Mollusca + Amphipoda</li> <li>6. Beck's Biotic Index (BBI)</li> <li>7. % filterers</li> </ol>	<ol style="list-style-type: none"> <li>1. # of genera</li> <li>2. % non-insect genera</li> <li>3. % sensitive EPT</li> <li>4. # of scraper genera</li> <li>5. Hilsenhoff Biotic Index (HBI)</li> <li>6. # of Attribute 2 genera</li> <li>7. # of Attribute 3 genera</li> </ol>

See METHODS, Table 1, Volume 1.

### Other notes:

1. Ck – Creek, Bk – Brook, Br – Branch, R – River, UNT – un-named tributary
2. Habitat observations supplement the habitat assessment scores in Table 2 and Appendix C; Open Canopy = overhead vegetation; water quality measurements taken in field include temperature (°C), pH, dissolved oxygen, conductivity.

\* (EPT organism) Taxa Richness: 23 Population: 100

Hilsenhoff Biotic Index (HBI): 5.94 # Scrapers: 2

% Sensitive EPT: 14.0% Attribute 2 genera: 3

% Non-Insect Taxa: 21.7% Attribute 3 genera: 1

HGMI Rating: 38.78 Fair

Habitat Analysis: 100 Marginal USEPA Protocol

Observations: Water temp: 17.07 C; Cond: 313 umhos; DO: 7.18 mg/L; pH: 7.50 SU

Clarity: clear; Flow Rate: slow; Width/Depth: 48' / 2-3'; Substrate: cobble, mud, snags

Canopy: open; Bank Stability: poor; Bank Vegetation: grasses, weeds

Stream Gradient: High Gradient Stream; Land Uses: agriculture-livestock

Pipes / Ditches: storm sewers

Other: fish, waterfowl, purple loosestrife, cows grazing at stream bank

AMNET Site # AN0308

Stream Name: UNT to Clove Bk

Location: Rose Marrow Ave nr Rt 651; Wantage Twp; Sussex County

Collection Date: 6/5/2008 USGS Topo Map: Unionville

<i>Genus</i>	<i>Tolerance Value</i>	<i>Amount</i>
Hyaella	8	27
Cricotopus	7	18
Nais	8	11
Rheotanytarsus	6	6
Caecidotea	8	5
Physella	9.1	4
